Next-Season Projections

Athlete: Athlete Report Date: June 24, 2026 Transition: Junior → Senior Sex: Female

🏃 Short Sprint Specialist (55–100m)

Event	Current Best	Projected Next Season	Expected Range	Historical Fit
55m (indoor)	8.24s	8.23s	8.11–8.35s	Strong
55m Hurdles (indoor)	9.66s	9.58s	9.34–9.82s	Strong
100m Hurdles (outdoor)	16.17s	16.14s ★	15.27–17.02s	Elite (56% improved)

★ Peer estimate — based on athletes at a similar performance level. See individual event pages for details.

SUMMARY

Across all three projected events, the models collectively suggest this athlete enters her senior year as a versatile sprinter-hurdler with a profile that is already well-developed relative to comparable athletes. The 55m projections point to potential improvement beyond her junior-year mark, with combined-event models estimating meaningfully faster times than the direct same-event model, making the senior sprint season worth watching closely. In the hurdle events, the models present a wider range of estimates, particularly for the 55m Hurdles, indicating more uncertainty in those projections, while the strongest-fit hurdles models generally cluster in a plausible improvement zone above her current bests. The 100m Hurdles picture is the most internally consistent of the three, with the direct model, highest-fit model, and elite peer comparison all converging near her junior-year performance level and suggesting incremental rather than large gains. Taken together, the projections paint a picture of an athlete approaching the upper range of typical junior-to-senior development in sprint and hurdle events, with the most meaningful upside potentially coming from events where combined-event models carry the strongest fit.

About these projections: Estimates are based on historical athlete-year transition data from western New York region high school meets and reflect typical development patterns. They do not account for every individual factor (health, training load, weather, race conditions, etc.). These projections are intended as a data-informed starting point for coaching conversations, not as exact predictions. Individual results may vary.

COACH'S NOTES

The direct same-event model projects a senior-year 55m of 8.23s (range 8.11–8.35s, $R^2=0.968$), essentially matching her junior-year best of 8.24s and suggesting modest improvement at this distance. However, the highest-fit model, built on combined 55m and 100m performances, carries a slightly stronger fit ($R^2=0.978$) and estimates 8.08s with a range of 7.98–8.17s, making it the most reliable reference point in this report. The 100m-only cross-event model projects even faster at 7.96s, though its range extends down to 7.85s and up to 8.08s, placing it on the optimistic end of the picture. Taken together, the cross-event models estimate meaningfully faster outcomes than the direct same-event model, and the models as a whole span a fairly wide band from the high-7s to the mid-8s; the combined 55m+100m model may be the most useful estimate to emphasize given its fit, while the direct same-event model remains the clearest event-specific comparison. Coaches should note that cross-event projections reflect performance relationships across athletes and should be interpreted as related-event estimates rather than certainties.

Model Projections · 55m Hurdles (indoor)

COACH'S NOTES

The direct same-event model for the 55m Hurdles projects 9.58s (range 9.34–9.82s, $R^2=0.935$), and the combined 55m+55mH model estimates a similar 9.53s. These two are quite consistent with each other and provide a reasonable event-specific baseline. The highest-fit model, combining 55mH and 100mH performances ($R^2=0.969$), projects a faster 9.25s (range 9.11–9.39s) and, as the strongest-fitting model, may better reflect her broader hurdles profile; it is worth emphasizing alongside the direct estimate. Several hurdles-based cross-event models (100mH+100m (9.03s), 100mH (9.07s), and 100mH+400mH (8.88s)) project noticeably faster outcomes, suggesting that if her outdoor hurdles performances are strong, her 55H ceiling may be higher than the direct model alone implies; however, these should be interpreted as related-event estimates and treated with appropriate caution. At the other end, the other models (55m, 100m, 400mH) project slower outcomes in the 9.77–10.00s range with lower fit values, and carry less weight here. Overall, the spread across models is fairly wide, from the high-8s to nearly 10 seconds, so this projection picture should be interpreted with more caution than a tightly clustered set of models would warrant.

● Model estimate ◆ Current Season Best: 16.17s

COACH'S NOTES

The direct same-event model projects a senior-year 100m Hurdles of 16.11s (range 15.70–16.52s, $R^2=0.950$), essentially in line with her junior-year best of 16.17s and suggesting only marginal improvement based on her 100H performance alone. The highest-fit model, combining 55mH and 100mH results ($R^2=0.954$), estimates a slightly slower 16.29s and notably close to the direct model, with the two together suggesting a reasonable central estimate somewhere in the 16.1–16.3s range. The combined 100mH+100m model (16.02s, $R^2=0.952$) and 100mH+400mH model (15.81s, $R^2=0.946$) both project modestly faster outcomes, indicating that if her sprint and longer hurdle performances are factored in, there may be somewhat more room for improvement; these are strong-fit cross-event references worth noting. Sprint-only and flat-sprint models estimate considerably slower times in the 17–18s range with lower fit values, and carry less interpretive weight for this event. The elite peer estimate of 16.14s (drawn from 39 comparable athletes, with 56% improving) suggests she was already performing near the level of similar athletes in her junior year, which helps explain why the projections cluster tightly and point to modest rather than dramatic gains; the models are fairly consistent, and a projected senior range of roughly 15.8–16.3s reflects the most reliable portion of the picture.

How to Read This Report

These projections estimate next-season performance from historical patterns — how thousands of similar high school athletes in the region have progressed from one season to the next. They are a data-informed starting point for coaching conversations, not predictions or promises. Here is what each term and symbol means.

THE SUMMARY TABLE & EVENT CARDS

Current (Season) Best — the athlete's fastest entered time this season for that event.

Projected Next Season — the model's single best estimate — the middle of the likely outcomes.

Expected Range — the band the result is most likely to land in. A wider band means more uncertainty for that event.

Transition — the grade-to-grade change the projection covers (e.g. Junior → Senior).

HISTORICAL FIT

A plain-language rating of how closely the model has matched *past* results for that event. It describes the strength of the historical pattern the estimate rests on — *not* how accurately the model will predict any one athlete's next season:

Strong R^2 0.90+ · **Good** 0.80–0.89 · **Fair** 0.70–0.79 · **Limited** below 0.70

PEER ESTIMATE VS. POPULATION MODEL

Population model — an estimate built from the entire historical group of athletes.

Peer estimate (★) — an estimate built only from athletes who were at a similar level (within a small window of this athlete's current best). For an athlete already near the top of the field, this peer group is usually a more realistic comparison than the full population.

Improved — the share of those similar athletes who actually got faster the following season, with the average change.

HOW THESE PROJECTIONS ARE CALCULATED

The projections come from statistical models fit to historical high school meet results from the western New York region, across many seasons and thousands of athletes. The models learn how an athlete's season in one year relates to their performance the next year. For each event, the model summarizes the season with three numbers:

Season best the fastest time that season · **Season trend** the average direction and rate of change across the season's meets (improving or fading) · **Curvature** whether that change was steady, accelerating, or leveling off

Because the trend and curvature are read from the *sequence* of meets, the order of an athlete's results across the season matters. A **same-event projection** uses the athlete's own history in that event; **cross-event projections** combine two related events (for example, the 200m and 400m to inform the 300m), since sprint and hurdle performances tend to move together. Each model appears as its own row on the event chart with its fit (R^2).

The next-season models are mixed-effects regressions, which account for the fact that athletes develop at different rates. The projected time is the model's central estimate; the expected range reflects the historical spread of next-season results for comparable athletes.

READING THE MODEL CHART

Each row is a different model — a different mix of events used to make the estimate (for example, using the 200m and 400m together to estimate the 300m).

Dot & horizontal bar — the dot is that model's estimate; the bar shows its expected range.

Gold diamond & dotted line — the current-season best, for reference.

"FIT R^2 " (MODEL FIT)

The small **fit R^2** under each model is a score from 0 to 1 of how closely that model's pattern has matched real results in past data. Higher means the relationship has been more consistent historically — a model at 0.95 rests on a tighter, more dependable pattern than one at 0.70. It describes the historical fit of the pattern, *not* a guarantee for any one athlete.

Move, Measure, Analyze LLC

Sprint development, measured.

Let's turn this data into a plan

This report is a starting point. We provide one-on-one sprint development consultation for athletes, parents, and coaches — helping interpret performance trends, identify event strengths, and build a speed-focused training plan around the athlete's goals.

We also bring the **sports science lab to you** with mobile force-plate testing — objective measures of force production, jump performance, reactive strength, braking and propulsive qualities, and left-right asymmetries to help inform training priorities.
